WHAT IS SCABIES?
Scabies is a contagious skin condition caused by tiny mites *Sarcoptes scabiei* that burrow into the skin. The main symptom of scabies are intense itching and a skin rash on areas where the mites have burrowed. The intense itching associated with scabies is thought to be caused by the immune system reacting to the mites and their saliva, eggs and faeces. Without effective treatment, the life cycle of the scabies mite can continue indefinitely. Scabies mites are resistant to soap and hot water and can't be scrubbed out of the skin.

HOW SCABIES SPREAD
Scabies mites can be transmitted by:
- Prolonged direct skin contact (>10min, often through hand holdings)
- Having sex with an infected person
- Rarely transmitted by contact with contaminated clothes, towels and bedding.

There’s an increased risk of catching scabies in confined environments, such as schools or nursing homes, where people are in close proximity to one another.

SYMPTOMS OF SCABIES
It may take 2 - 6 weeks to develop sign of scabies. Symptoms will start within 1 to 5 days if you’ve had a scabies infection in the past.
- **Burrow marks** - a small red blotches and silvery lines (2 - 10mm long) with a black dot at one end that can be seen with a magnifying glass. Commonly occur in the loose skin between the fingers (the web spaces), the inner surface of the wrists, elbow, and the hands or the soles and sides of the feet.
- **Intense itching** which is often worse at night, or after a hot bath or shower.
- **Pimple-like rash** - commonly found in the underarm area around the waist, inside of the elbow, the lower buttocks, the lower legs, the soles of the feet. the knees, the shoulder blades, the female genital area, the groin and around the ankles. In infants and young children, burrow marks tend to appear in different places on their body, including on the face, head, neck, scalp, palms of the hands and soles of the feet.
- **Scales or blisters**—may develop on the soles of the feet and palms of the hands infants with scabies.
- **Sores** caused by scratching . An infection can develop in the sores.

CRUSTED (NORWEGIAN) SCABIES
It is an uncommon form of scabies. It is highly contagious with huge numbers of mites and more common in immunocompromised and neurologically impaired individuals. Pruritus may be minimal or absent. Characterized by diffuse hyperkeratosis, associated with variable degree of underlying erythroderma. Hyperkeratosis and crusting are particularly severe on the hands, including the palms and soles, under the fingernails, on the ears, trunk and extremities.

7 April 2016, Kelantan- Adam Bukhari Mohd Jazal, 6, accidentally drank the Lindane Lotion prescribed for his scabies treatment due to the wrong labelling on the lotion. One of the clinic wrongly attached the label for CO-AMOXICLAV 228MG/70ML on the lindane lotion and vice versa. Therefore, the mother of Adam Bukhari Mohd Jazal followed the instructions on the label and administered 5mL of Lindane lotion to her child orally at 12am on 4 April and applied the CO-AMOXICLAV suspension on the site affected. After 2 hours, Adam started to feel dizzy and stomach ache but the mother just gave him paracetamol. On the next day 12pm, the mother gave Adam a second dose of Lindane lotion orally. After 2 hours, Adam experienced muscle cramps and both of his eyes turned upwards. Adam was then quickly admitted to hospital for treatment.

**CAN LINDANE BE USED TO TREAT SCABIES?**

Lindane 1% Lotion/cream (Gamma benzene hexachloride) is an organochloride. Although FDA-approved for the treatment of scabies, lindane is not recommended as a first-line therapy. Overuse, misuse, or accidentally swallowing lindane can be toxic to the brain and other parts of the nervous system. Use of lindane should be restricted to patients who have failed treatment with or cannot tolerate FDA-approved topical medications for the treatment of scabies. If used for classic scabies, two doses of oral ivermectin (200ug/kg/dose) should be taken with food, each approximately one week apart. The safety of ivermectin in children weighing less than 15 kg and in pregnant women has not been established. Note that although ivermectin guidelines recommend taking on an empty stomach, scabies experts recommend taking with a meal to increase bioavailability.

**IMPORTANT:** Scabicide should be applied to all areas of the body from the neck down to the feet and toes. In addition, when treating infants and young children, scabicide also should be applied to their entire head and neck because scabies can affect their face, scalp, and neck, as well as the rest of their body. The scabicide should be applied to a clean body and left on for the recommended time before washing it off. Clean clothing should be worn after treatment.

Because the symptoms of scabies are due to a hypersensitivity reaction (allergy) to mites and their feces (scybala), itching still may continue for several weeks after treatment even if all the mites and eggs are killed. If itching still is present more than 2 to 4 weeks after treatment or if new burrows or pimple-like rash lesions continue to appear, retreatment may be necessary.

**Oral Ivermectin**

Ivermectin is an organochloride. Although FDA-approved for the treatment of scabies, lindane is not recommended as a first-line therapy. Overuse, misuse, or accidentally swallowing lindane can be toxic to the brain and other parts of the nervous system. Use of lindane should be restricted to patients who have failed treatment with or cannot tolerate other medications that pose less risk.

**Dosing:**

- Oral ivermectin should be considered for patients who have failed treatment with or who cannot tolerate FDA-approved topical medications for the treatment of scabies. If used for classic scabies, two doses of oral ivermectin (200ug/kg/dose) should be taken with food, each approximately one week apart. The safety of ivermectin in children weighing less than 15 kg and in pregnant women has not been established.

**Additional measures:假冒));

1. **Pediatric**

   - Patients may need admission.
   - Strict control to prevent spread of infection.

2. **Adult**

   - Treat all family members/close contacts simultaneously.

**Side effects:**

- Neurotoxicity; Cramps, dizziness, seizures in children.
- Hypoplastic anaemia and cancer.

**Precautions:**

- Do not use Lindane Lotion more than 1 time to treat an attack of scabies or to treat a second attack of scabies that comes soon after the first episode.
- Use it more than 1 time can cause seizures and death. Even if you still itch after using Lindane Lotion, do not use more or use it again. Scabies (bugs) can make your skin itch for a few weeks even after all of the bugs are dead.
- If you are putting Lindane Lotion on another person, wear special gloves made of nitrile, latex with neoprene, or sheer vinyl. Do not use natural latex gloves because more lindane can go through that kind of glove.
- Wash your hands well when you are done.
- Make sure your skin is clean and does not have any other lotion, cream, or oil on it. Oils can make Lindane Lotion go through your skin faster and may increase the risk of seizures.
- Wait for at least 1 hour after bathing or showering before you put Lindane Lotion on your skin. Wet or warm skin can make the Lindane Lotion go through your skin faster and may increase the risk of seizures.
- The drug should be applied from the neck downwards all over the body. The most common mistake is that the drug is applied only to the affected areas, which leads to a relapse of the disease. The drug dispensed should not be diluted.

**Treatment for infestations**

- Underwear, clothing, towels and slippers used by the affected person in the 72 hours prior to treatment should be laundered using a hot wash cycle (>50°C) or hot tumble dried to kill the mites.
- If items are unable to be laundered or hot tumble dried, place them in a plastic bag for 72 hours before airing and reusing.
- Mattresses should be thoroughly vacuumed, ironed or steam cleaned, paying particular attention to the seams.
- Where possible, amenities such as toilets and chairs should not be shared (until 24 hours after the first treatment).
